ABSTRACT

This data report presents summaries of measurements made with current meters in Long Island Sound by researchers from the Marine Sciences Research Center during 1988. This effort is part of the Long Island Sound Study, a National Estuary Program conducted by the U.S. Environmental Protection Agency.

The objective of these observations was to determine spatial and temporal scales of the circulation and field of density in the Sound and to provide calibration data for numerical modelling studies.

The report includes a description of the instruments, discusses the data reduction and presents the time series as well as some basic statistics.

1. Introduction

The measurements presented in this data report were made during 1988 and are part of the data collection program of the Long Island Sound Study, sponsored by the U.S. Environmental Protection Agency under the National Estuary Program.

Confined between the Connecticut and Long Island coasts and having New York City as its western boundary, the 110 mile long Sound is surrounded by 15 million people (Fig.1). This "urban sea" (Koppelman et al., 1976) has been under tremendous environmental stress as its water quality deteriorates and its fishing grounds are increasingly threatened. The Long Island Sound Study was conceived to protect and improve the health of the Sound's resources and the water quality upon which they depend. It is the most extensive and comprehensive effort to collect data in the Sound ever undertaken. Along with historical information, these data will allow a thorough study of different aspects of the Sound's behavior. One fundamental aspect needing attention was the circulation and physical structure of the Sound's waters. Most current measurements in the Sound have been obtained in the past for the purpose of either investigating the characteristics of the oscillatory tidal currents in the surface layers of the Sound or determining the near bottom tidal and residual currents out of an interest for sediment transport. Lacking was a data base containing systematic current measurements capable of revealing the three dimensional distribution of the residual field of motion and of mass and which would also be suitable to support a numerical modelling effort (Bohlen et al., 1986).

Researchers from the Marine Sciences Research Center of the State University of New York at Stony Brook designed and executed a field program to collect such a data base.

2. Data acquisition and processing

Figure 1 shows the location of the moored arrays of current meters. These locations were designed to complement the deployment of RADS (Remote Acoustic Doppler System) instruments by the National Ocean Service of NOAA. A total of 96 instruments were deployed in 6 transects across the Sound between 28 March and 14 October 1988. The transects were occupied for about one month each, and then the array of instruments was moved and redeployed at the next section. The transects are numbered from 1 to 6 from West to East. The easternmost transects 5 and 6 were occupied simultaneously twice: in June and in September. Within each transect the moorings have designations N (North), NC (North Center), SC (South Center), C (Center) and S (South).

Based on previous information (Wilson and Vieira, 1981) it is reasonable to expect that the data obtained from such successive (i.e., non-synoptic) one month long deployments can be fitted together to provide a basis for understanding the three dimensional circulation pattern of the Sound.

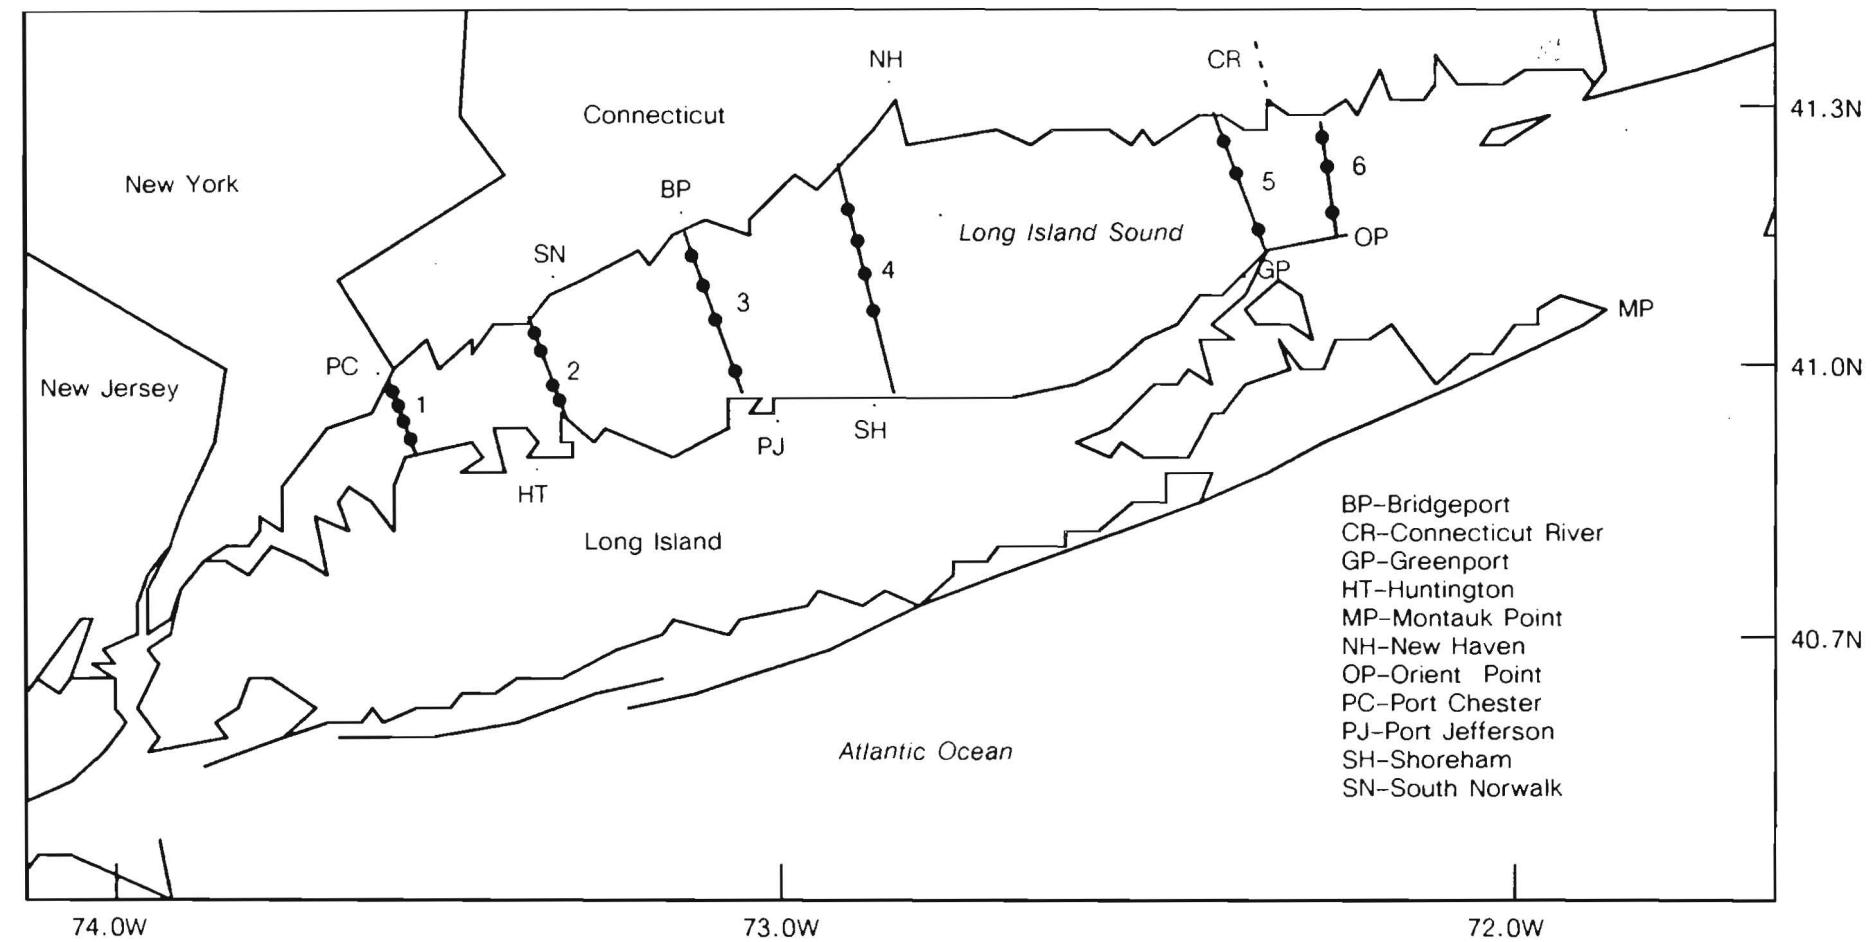

Fig. 1- Diagram of Long Island Sound showing the transects and positions of the moorings.

The instruments were deployed on taught wire vertical moorings. Railroad wheels were used as bottom weights along with a Danforth anchor. Tension was kept on the line by the use of submerged buoys (function of the number of instruments on the line), the topmost of which was kept at least 2 meters below the lowest water level. A marker buoy on a slack line served as aid in locating moorings in shallow water where barge traffic was not likely. For the deeper moorings, where the probability of damage was higher, there was no marker buoy. Instead, an MSRC designed and built time release was installed above the upper subsurface buoy; at the programmed release moment a small float, connected to the mooring, was released to the surface, allowing recovery of the array. The recovery rate in this heavily navigated waterway was excellent: 2 instruments were lost and 15 gave unusable records.

Even though the instruments had been treated with antifouling paint, biofouling of the speed and conductivity sensors was a source of difficulty, especially during the summer deployments.

The machines utilized were of two types. The Endeco 174 can move freely tethered to the wire; it recorded current speed and direction, temperature and conductivity, every two minutes on magnetic tape. The speed sensor is a horizontally mounted ducted impeller, giving an accuracy of ± 7.7 cm/s. The direction is sensed by a magnetic compass with an accuracy of $\pm 7.2^\circ$. The temperature sensor is a thermilinear thermistor with an accuracy of $\pm 0.2^\circ\text{C}$, while an inductive cell allows conductivity measurements accurate to within ± 0.055 s/m (0.55 mmho/cm). A detailed description of the instrument is given in Endeco(1978).

The Aanderaa RCM-4 records current speed and direction, temperature, conductivity and pressure every 5 minutes on magnetic tape. The speed sensor is a vertically mounted Savonius rotor with an accuracy of ± 1 cm/s. A magnetic compass determines the direction of the instrument which aligns itself with the current by means of a large vertical fin; accuracy $\pm 7.5^\circ$. A thermistor measures temperature to a $\pm 0.05^\circ\text{C}$ accuracy. Conductivity is determined by an inductive cell to an accuracy of ± 0.0025 s/m (0.025 mmho/cm). The pressure readings were not reliable, even after calibration; the pressure signals were useful only from a qualitative point of view, and as such are not included in this report. The instrument is described in Aanderaa (1981).

All current meter sensors were calibrated prior to the first deployment in March 1988. Calibration of the speed sensors and related electronics was done in a flume with variable flow. The magnetic compasses were calibrated by comparison with azimuths determined by theodolite. Temperature and conductivity calibrations were performed in the MSRC calibration tank whose temperature was allowed to vary over a wide range, but accurately stabilized and measured with a standard bridge at each stop point. The conductivity was made to vary as the tank temperature changed, while the salinity of the bath at each stop point was

determined from samples taken from the tank and analyzed in a Guildline Autosal bench salinometer. A regression analysis was performed between sensor readings and reference standard; polynomial fit coefficients were thus determined for application to the data when running calibration programs. Calibration curves for both types of instrument had typical standard errors on the order of 0.03°C for temperature and 0.006 s/m (0.06mmho/cm) for conductivity.

The magnetic tapes retrieved from the instruments were read and the data transferred to computer tapes. The records were then submitted to the MSRC data processing routines, consisting of calibration and quality control programs. All time series were plotted before and after calibration and the data edited to remove bad points, which were replaced by linearly interpolated values. Timing was checked against the field log and gaps and sensor malfunctions were identified. Salinities were computed from the simultaneous temperature and conductivity data according to the PSS78 algorithm.

3. Data presentation

The data is presented for each transect, from West to East. Within each transect it is grouped by mooring, from North to South. Within each mooring it is arranged from top to bottom.

There is a one page summary for each instrument, containing the following information. The type of instrument and its serial number are listed. The station numbers correspond to the moorings shown in Figure 1; the geographical coordinates are also indicated. A sketch of the location of the current meters in each transect is also provided (Figs. 2-9); the unlabeled positions correspond to instruments which did not yield usable records.

The depth of the instrument and that of the water at that station are given in meters below Mean Low Water (MLW). The start and stop times of the time series are in local time for the 75°W meridian (i.e., Eastern Standard Time), as are all times throughout this report. The duration of the time series is the difference between the start and stop times. The sampling interval is the time elapsed between adjacent recordings of the instrument.

Other peculiarities of the record or comments on the perceived quality of the time series are noted under "Comments". The last section of this first page is a summary of various statistics.

The following pages contain computer generated scatter plots, progressive vector diagrams, time plots of the temperature and salinity time series and also of the along transect and cross transect velocity components.

4. Statistics

The following statistical parameters are calculated for the respective number of data points stated, in the units indicated.

If there are N values in a record of the variable x, define

$$\text{Mean } \bar{x} = \frac{1}{N} \sum_{i=1}^N x_i$$

$$\text{Variance } \sigma^2 = \frac{1}{N-1} \sum_{i=1}^N (x_i - \bar{x})^2$$

$$\text{Standard deviation } \sigma$$

These parameters are presented for the along-transect and the cross-transect components of the current velocity (positive directions indicated under "current component towards"), as well as for the temperature, salinity, the scalar Speed and the velocity vector where

$$\text{vector mean } \bar{v} = \sqrt{\overline{(\text{East})^2} + \overline{(\text{North})^2}}$$

$$\text{vector variance } \sigma_v^2 = \frac{1}{2} (\sigma_{\text{East}}^2 + \sigma_{\text{North}}^2)$$

$$\text{standard deviation } \sigma_v$$

The maximum and minimum values of the variables are also presented.

5. Scatter plots

The tip of the velocity vector at each point in time is plotted on cartesian coordinates oriented to true North at the top of the picture. For the purpose of generating these plots the time series were decimated to intervals of 10 minutes.

These diagrams are useful in interpreting certain features of the flow, such as non-parallelism of flood and ebb and asymmetry of their respective velocity variabilities, as well as in detecting instrument idiosyncrasies and malfunctions.

6. Progressive vector diagrams

Spatial displacements are computed from the speed and direction values of the velocity vector during each sampling interval and are plotted in sequence. The plot begins with a \diamond ; each 24 hour period from then on is indicated by a $+$. True North is at the top of the picture.

These diagrams accentuate the low frequency circulation events

related to the density structure and meteorological forcing, while still depicting higher frequency, intratidal flow features.

7. Time plots

These are representations of the velocity components, temperature and salinity as a function of time. The along transect component of the velocity is positive towards the Connecticut shore, while the cross transect component is positive towards the Race. These directions are indicated in the summary page under "current component towards".

This type of plot complements the progressive vector diagram in that it emphasizes higher frequency events, particularly at tidal frequencies. The apparent "steppiness" of some of these time series results from the scale of the plot being large in relation to the resolution of the instrument.

It also appears that the instruments (particularly the Aanderaas) were adversely affected by biofouling of both the speed and conductivity sensors, especially during the summer deployments. Even though the machines had been properly coated with antifouling paint, this is not surprising given the high productivity of these estuarine waters at that time. Typically the velocity components will show a progressive decay in the amplitude, while the salinity starts plunging rather abruptly.

No effort was made to remove the "spikiness" present in several time series, particularly temperature and salinity. This is in great part due to noise and may be removed by appropriately designed high pass filters.

For the purpose of generating these plots the Endeco 174 records were decimated to intervals of 6 minutes.

Note: the currents at transects 5 and 6 can be very large, with the result that moorings 5C, 5S, 6C and 6S suffered large angular displacements from the vertical due to the drag on the hardware. This effect was quite severe at times, leading to large vertical displacements of the instruments (a maximum of about 9 meters was deduced from the pressure signal). Such fact should be kept in mind whenever the instrument depth may be important for the interpretation of the data.

8. Acknowledgements

The principal investigators in this project were Donald W. Pritchard and Mário E. C. Vieira.

The project owes its success to the collaboration of several people. We want to show our appreciation to Tom Wilson and Henry Harrison for dispensing copious amounts of tender, loving care to the instrumentation. We thank Captain Helmut Stuebe and mate Bret Zielenski for their safe and efficient conduction of the mooring operations onboard the R/V Onrust, as well as Mark

Wiggins for his expert assistance with the preparation and deployment of the arrays. The participation of Eugenio Gomez-Reyes, Richard Muller and Jonathan Salerno is gratefully acknowledged. Our thanks also to George E. Carroll for his thorough and patient handling of the data reduction.

This project was supported by the U.S. Environmental Protection Agency as part of the National Estuary Program's Long Island Sound Study.

Comments:

These records are presented subjected to certain constraints.
There is a discrepancy of 12 hours 45 minutes between the
record length and the start and stop times from the log.
Being so close to a tidal period, it was not possible to
identify the exact location of the missing data points.

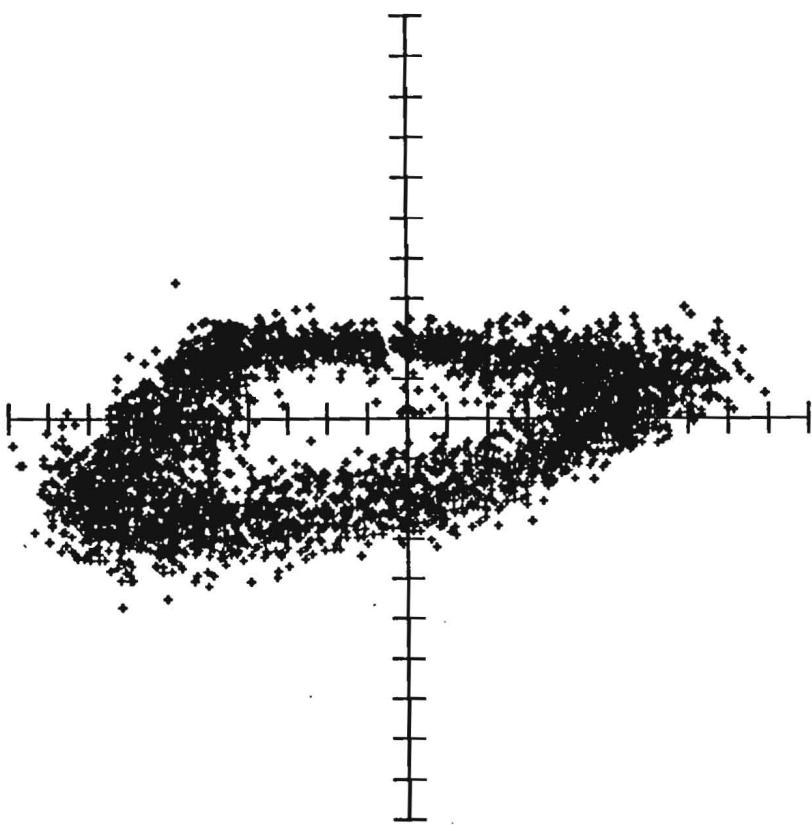

The use of these time series is not recommended in applications
where timing or phase considerations may be important.

Station 6N , 41 15.4N 72 16.6W

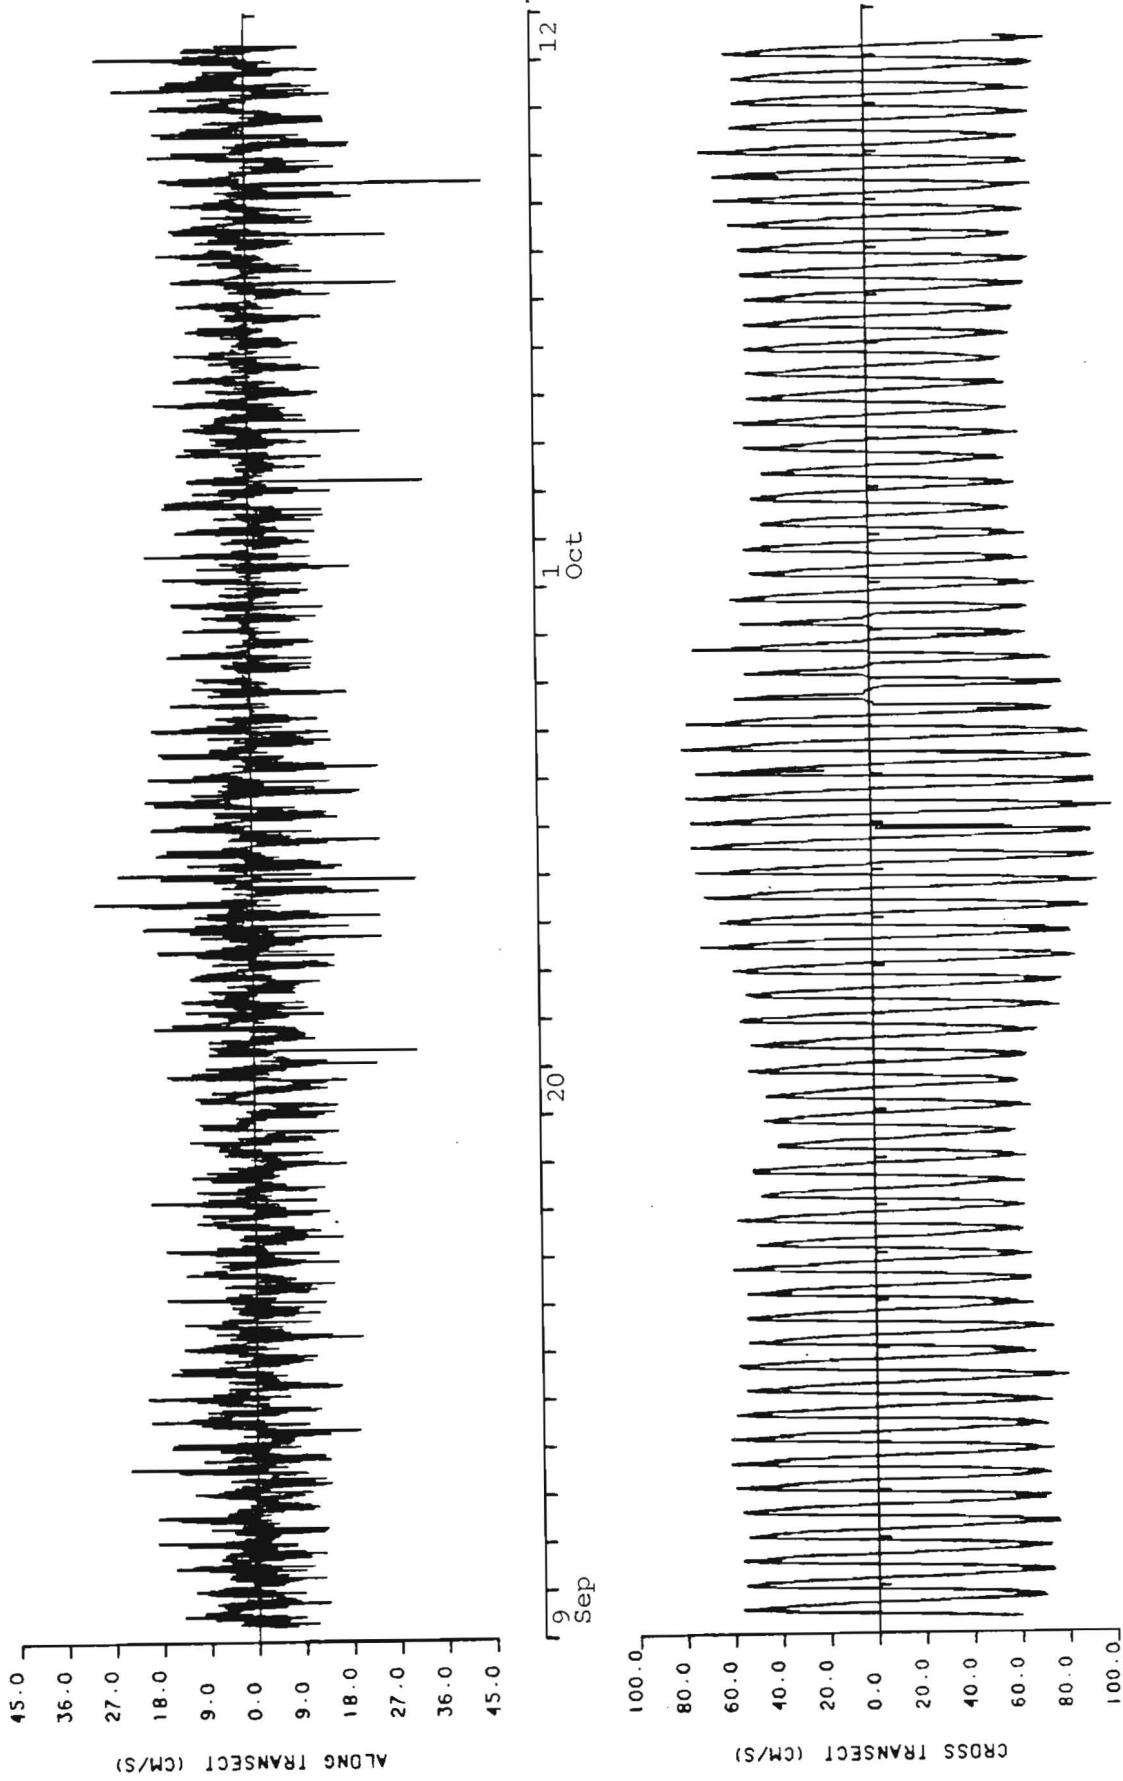

Instrument depth(below MLW) = 13.1 m

Water depth(relative to MLW) = 17.7 m

SCALE = 9.5 CM/S PER TICK

Current meter : ENDECO #1740112
Station # and location : 6C , 41 13.5N 72 15.9W
Instrument depth (MLW) : 3.4m
Water depth (MLW) : 42.7m
Start time : 09/08/88 15:14 EST
Stop time : 10/11/88 11:50 EST
Duration : 32 days 20 hours 36 minutes
Sampling interval : 2 minutes

Comments:

Conductivity malfunctioned.

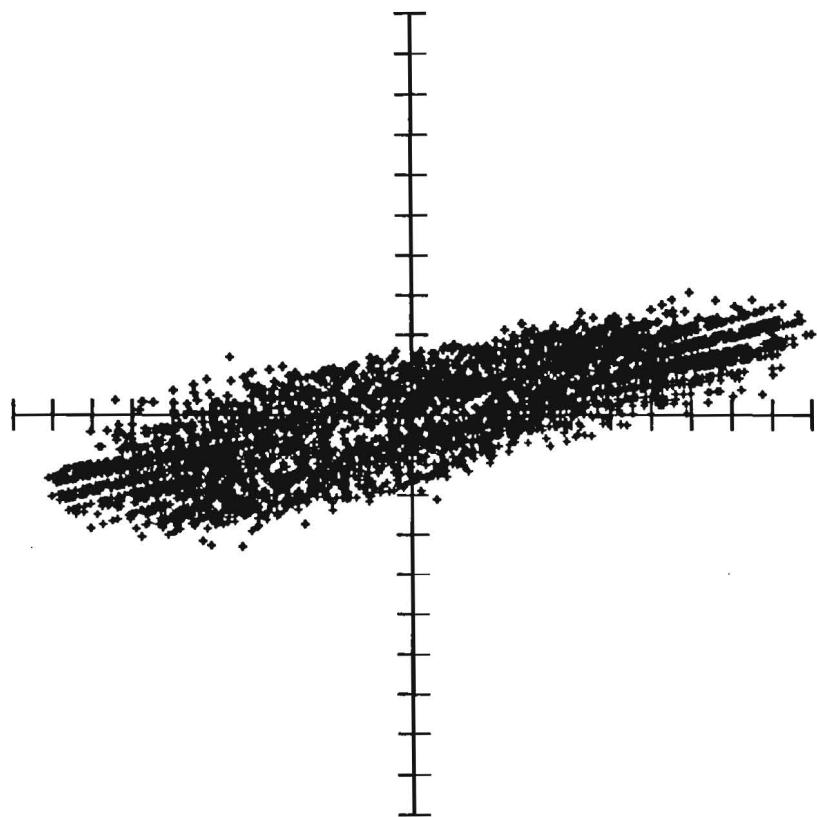

Speed gap from 30 September to 2 October; low reliability of velocities beyond 2 October.
